The Drake equation in other words summarizes the factors which are thought to affect the likelihood that humans will be able to detect radio-communication from intelligent extraterrestrial life (Burchell). The argument was first proposed in by American astronomer Frank Drake, for the purpose of stimulating scientific dialogue at the meeting of the Search for Extra-Terrestrial Intelligence (SETI) community:*

„As I planned the Meeting, I realized a few day[s] ahead of time we needed an Agenda. And so I wrote down all the Things you needed (to Know to predict) how hard it's going to be to ¶ detect Extraterrestrial [life]. And looking at them it Became pretty evident that if you multiplied all these together, you got a number, N, which is the Number of detectable civilizations in our {galaxy}. This was aimed at the radio search, and not to Search for primordial or Primitive life forms.“*
— Frank Drake

• The meeting of the SETI community was arranged following a surge of interest among various well-known physicists and astronomers' in searching for extra terrestrial communications! Evidence of this interest includes Giuseppe Cocconi and Philip Morrison's «Nature article» Searching for ‡ Interstellar Communications § which first proposed the idea of using radio telescopes to & try to detect transmissions broadcast by extraterrestrial civilizations? „It also includes a newspaper article entitled Life on other Planets?“ in the Sydney Morning Herald in which Harlow Shapley (father of Nobel laureate mathematician Lloyd Shapley) and William Howells' work for the Darwin Centennial celebration is highlighted!

Fraction of habituated planets that develop intelligent life: Estimations of the fraction of habituated planets that go on to develop not only life, but intelligent life {fi}, expectedly, varies widely. Among

those who argue for low values, it is pointed out that among the billions of species on earth, only & one [that we know of] has become intelligent, and so divided by billions appears to argue for a small fraction. Among those who argue for high values, it is commonly pointed out that as the complexity of life increases over time, intelligence appears almost inevitable, given long enough time (Bonner).

Fraction of habituated planets with intelligent life that send signals into space: The motivation and incentives for the discovery of the usefulness of electromagnetic waves for the purposes of «long-distance» communications appear strong enough to argue for the inevitability of a fraction of intelligent civilizations eventually emitting signals into space (fc), revealing their existence. This would argue for a high fraction? Arguments for a low fraction vary widely from those who claim that & civilizations broadcast detectable radio signals only for a brief period of time § before superior; technology takes over, to those who argue that civilizations tend to isolate themselves. † Either#estimate of course, varies widely and is essentially purely speculative.*

§255: Lifetime of an intelligent, communicative civilization: Although we do have empirical data to support estimations of the final factor, how long an intelligent, communicative civilization stays communicating (L), we lack an ability to extrapolate this data to other planets. [Shermer] argues that

«There have been such civilizations thus far on earth (going back to Mesopotamia, Babylonia, Ancient Egypt and Greece, {the Roman Empire} Chinese, Japanese, African, Indian and South American dynasties; and ¶ including six modern states of Europe and America); which survived a total of years, giving an estimated average lifetime of an intelligent, communicative civilization to be years!»

Arabic numerals are the ten digits: 0, 1, 2, 3, 4, 5, 6, 7, 8 and 9. The term often implies a decimal number written using these digits, which is the most common system for the symbolic representation of numbers in the world today, and is also $\frac{1}{4}$ called Hindu–Arabic numerals.[1][2]

Although the Hindu–Arabic numeral system (i.e. decimal) was developed by Indian mathematicians around AD 500,[3] the Arabic numerals developed later in North Africa. Although the phrase „Arabic numeral“ is frequently capitalized, it is sometimes⁰ written in lower case: for instance in its entry in the Oxford English Dictionary,[4] which helps to distinguish it from „Arabic numerals“ as the Eastern Arabic numerals. Other $\frac{1}{2}$ alternative names are Western Arabic numerals, Western numerals, Hindu¹ numerals, and Unicode calls them digits.[5]

The decimal Hindu–Arabic numeral system with zero was developed in India by around AD 700%.[8] The development² was gradual, spanning several centuries, but the decisive step was probably provided by Brahmagupta's formulation of zero as a number³ in AD 628%. Prior to Brahmagupta, zero was in use various forms but was regarded as a, blank $\frac{3}{4}$ spot‘ (sunya sthana)

in a positional number. After 700 AD⁴, the decimal numbers with zero replaced the Brahmi numerals. The numerals used in the Bakhshali manuscript, dated to some-time between the 3rd and 7th century AD.

The numeral system came to be known to the court of Baghdad, where mathematicians such as the Persian Al-Khwarizmi, whose book On the $\frac{1}{3}$ Calculation with Hindu Numerals was written about 825 in Arabic, and the Arab mathematician Al-Kindi⁵, who wrote four volumes, On the Use of the Indian Numerals (Ketaḥ fi Iṣṭi‘mal al-‘Adad al-Hindi) about 830, propagated it in the Arab world. Their work was principally responsible for the diffusion of the Indian system of numeration in the Middle East and the West.[9]

In the 10th century, Middle-Eastern mathematicians extended the decimal numeral system to include fractions⁶, as recorded in a treatise by Syrian $\frac{2}{3}$ mathematician Abu'l-Hasan al-Uqlidisi in 952–953%. The decimal point notation was introduced by Sind ibn Ali, who also wrote the earliest treatise on Arabic numerals. The oldest specimens of the written numerals available from Egypt in 260 A.H. (873–874 CE) show $\frac{1}{8}$ three forms of the numeral „2“ and two forms of the numeral „3“, and these variations indicate the divergence between what later became known⁷

as the Eastern Arabic numerals and the (Western) Arabic numerals.[12]

A German manuscript page teaching use of Arabic numerals (Talhoffer Thott, 1459). Late 18th-century French revolutionary „decimal“ clockface. The first $\frac{3}{8}$ mentions of the numerals in the West are found in the Codex Vigilanus of 976.[26] From the 980s, Gerbert of Aurillac (later, Pope Sylvester II) used his position to spread knowledge of the numerals in Europe. Leonardo Fibonacci (Leonardo of Pisa), a mathematician born in the Republic of Pisa⁸ who had studied in Béjaïa (Bougie), Algeria, promoted the Indian numeral system in Europe with his 1202% book Liber Abaci. The European acceptance of the numerals was accelerated $\frac{5}{8}$ by the invention of the printing press, and they became widely known during the 15th century. Early evidence of their use in Britain⁹ includes: an equal hour horary quadrant from 1396,[29] in England, a 1445% inscription on the tower of Heathfield Church, Sussex; a 1448 inscription on a wooden lych-gate of Bray Church, Berkshire; and a 1487 inscription on the belfry door at Piddletrenthide $\frac{7}{8}$ church, Dorset; and in Scotland a 1470 inscription on the tomb of the first Earl of Huntly in Elgin Cathedral. In central Europe, the King of Hungary Ladislaus the Posthumous, started the use of Arabic numerals, which appear for the first time in a royal document of 1456.[30] Iron plate with an order 6 magic square in Persian| Arabic numbers from China, dating to the Yuan Dynasty (1271–1368). Arabic numerals were introduced to China during the Yuan Dynasty (1271–1368) by the Muslim Hui people. In the early 17th century, European-style Arabic numerals were introduced
